

POND AID**Pond Health Check**

Water quality is the most important aspect of keeping fish healthy.

If fish do not thrive and are constantly suffering from diseases, testing the water to check the basic stress causing factors is the first thing to do in order to solve the problem and stop it from happening.

Pond Health Check contains the 3 most important tests for keeping fish healthy:

pH - the level of acidity in the water can cause health problem especially if it changes suddenly. The pH should remain between 6 and 8 to make sure that fish are not stressed.

Nitrite - These are toxic by-products of the biological filtration process. Any level detected in pond water indicate possible danger to fish health and the filtration system needs to be investigated.

Ammonia - Levels of nitrite and ammonia can rise if too many fish are added to the pond at once or if too much food is given.

The Pond Health Check kit comes with a comprehensive instruction booklet.
